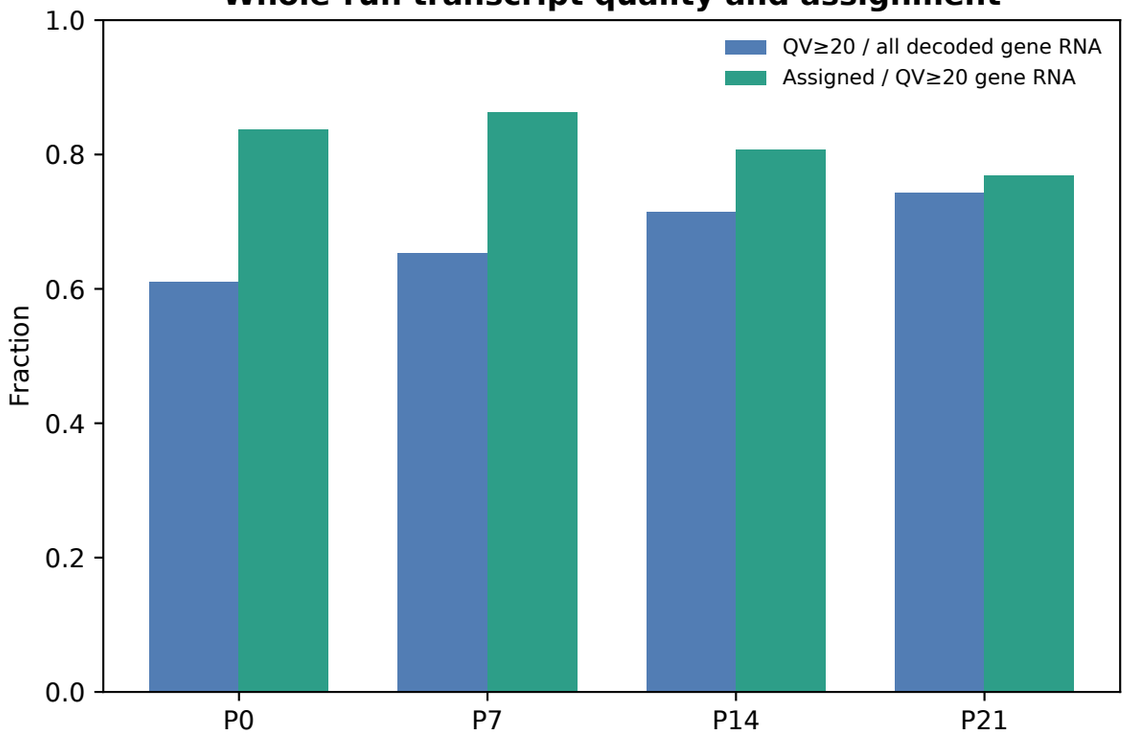
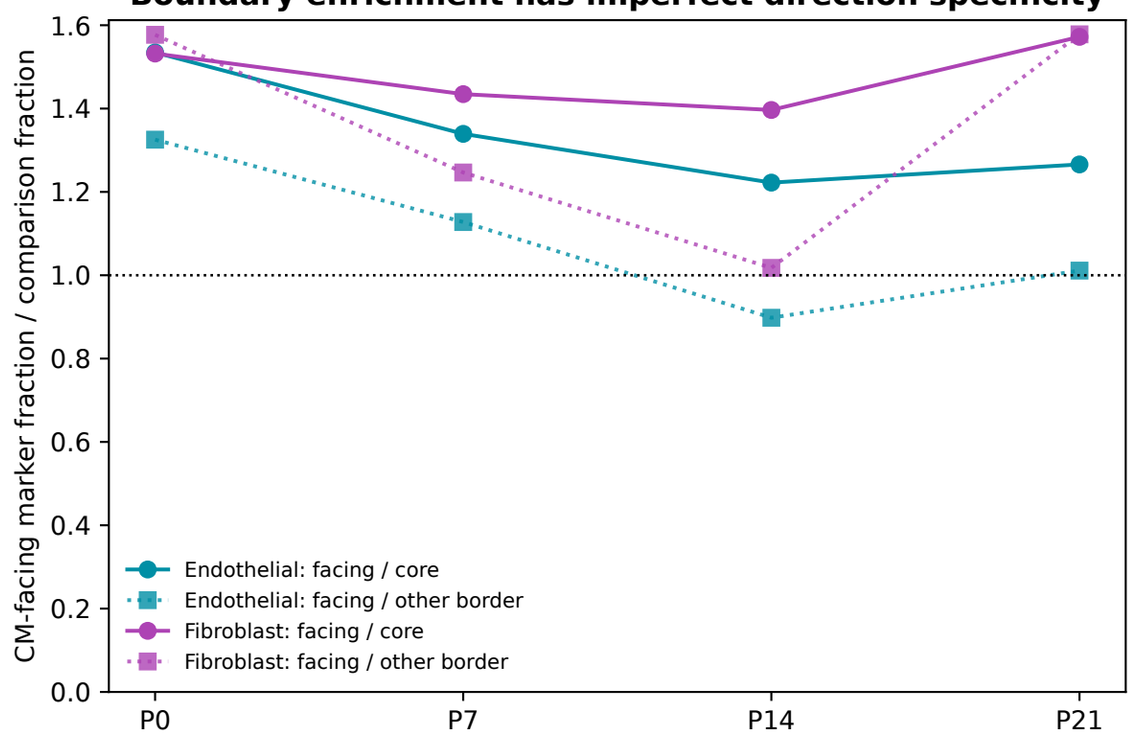
Xenium transcript-boundary audit and segmentation sensitivity

Whole-run transcript quality and assignment



Boundary enrichment has imperfect direction specificity



All 3,104 original matched CM pairs

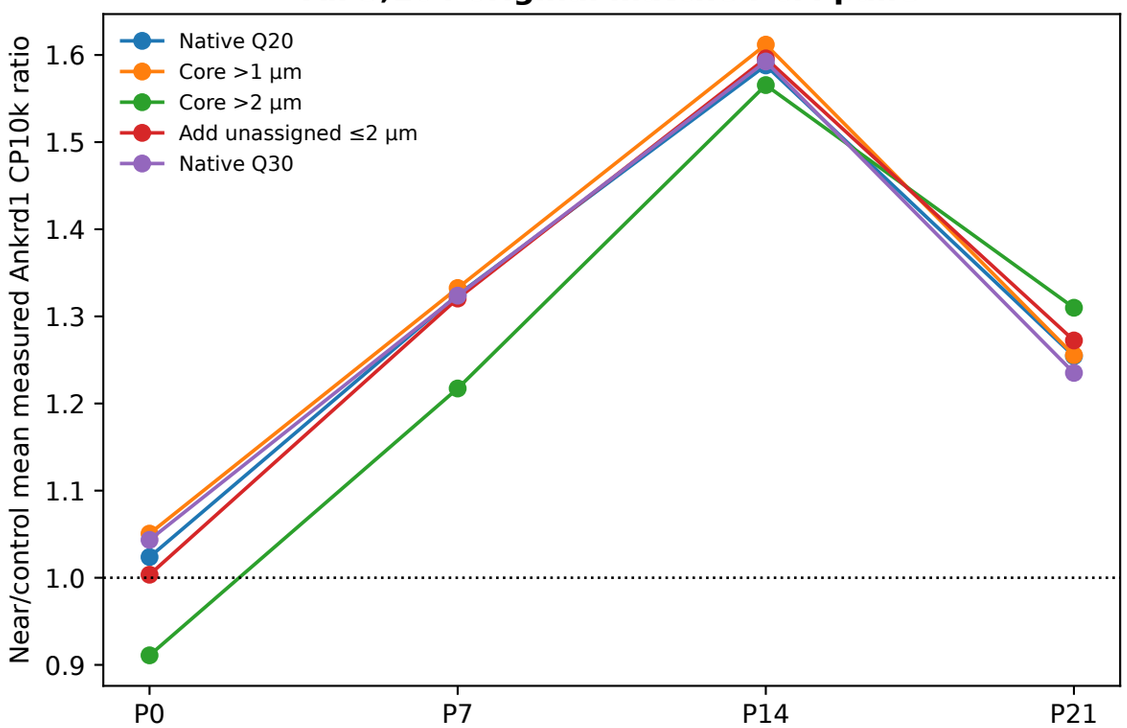


Image comparisons use the same smaller subset

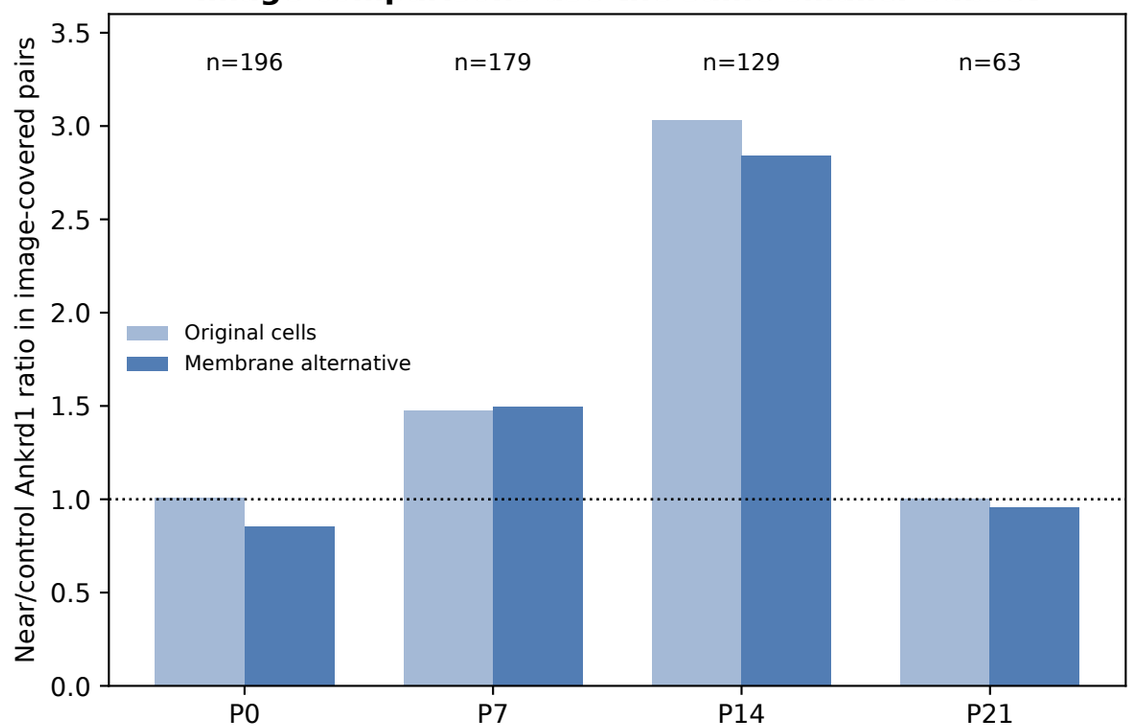

Molecule reconstruction matches every deposited count matrix exactly at QV≥20. No nucleus is required for a CM profile.
Boundary-localized marker RNA is compatible with mixing, not proof of contamination. Alternative segmentation is not validated ground truth.
One section per stage; ratios are within-section contrasts. Full-pair and image-region subsets must not be treated as the same cohort.
